

A financial model is a chain of judgements. An agent can be taught to hold that chain.

The book moves from the mechanics of language models to the architecture of agents — tools, memory, orchestration, and composability — and grounds every idea in the mathematics of financial theory. Each concept is built twice, once as a formula and once as code, using Python and Agno throughout.

By the final chapter, the reader will have designed, tested, and deployed a working agentic system— one that reasons about a financial question, selects the correct calculation, and explains its answer with the same rigor an actuary would demand. This book is a guide for anyone ready to think computationally about financial mathematics, and agentially about AI.
